

Preliminaries

The Bourgeois construction

Definition 1. Let M be an oriented manifold with an open book decomposition (B, p) with oriented binding B . The pages are oriented by the requirement that the induced orientation on the boundary of (the closure) of each page coincides with the orientation of B .

Question: I don't fully understand Geiges remark there (in Def 4.4.7).

A contact structure $\xi = \ker \alpha$ on M is said to be **supported** by the open book decomposition (B, p) of M if

- (i) the contact form α induces the positive orientation of M ($\alpha \wedge (d\alpha)^n > 0$).
- (ii) the 2-form $d\alpha$ induces a symplectic form on each page, defining its positive orientation
- (iii) the 1-form α induces a positive contact form on B , i.e.

$$\alpha|_{TB} \wedge (d\alpha|_{TB})^{(n-2)} > 0.$$

Theorem 1. Let $(M, \xi = \ker \alpha)$ be a closed contact manifold of dimension $2n - 1, n \geq 2$. One can find an open book decomposition (B, p) of M supporting ξ . According to Bourgeois, ([Bou02]) there is a contact structure $\tilde{\xi}$ on $M \times T^2$ (where $\tilde{\xi}$ massively depends on the choice of open book).

Proof. We follow the proof of [Gei08, Thm 7.3.6]. Wlog let M be connected. The existence of an open book decomposition for M is the theorem of Giroux-Mohsen as in [Gei08, Thm 7.3.5]. By definition of an open book, there exists a tubular neighborhood $B \times D^2$ with polar coordinates (r, ϕ) on the D^2 -part of the binding B s.t. $p : M \setminus B \rightarrow S^1$ is given by ϕ in that neighborhood. Now, we want to define smooth functions x_1, x_2 on M that coincide with the cartesian coordinate functions on D^2 close to the binding B . In order to do that, choose a smooth function $\rho(r)$ on $B \times D^2$, s.t.

- $\rho = r$ near the binding B ,
- $\rho'(r) \geq 0$
- $\rho \equiv 1$ near $B \times \partial D^2$.

We extend this function to a smooth function $\rho : M \rightarrow [0, 1]$ by setting $\rho \equiv 1$ outside $B \times D^2$. Now, $x_1 := \rho \cos \phi$ and $x_2 := \rho \sin \phi$ are the desired smooth functions on M that coincide with the Cartesian coordinate functions on the D^2 -factor near B . We compute

$$\begin{aligned} x_1 dx_2 - x_2 dx_1 &= \rho^2 \cos^2 \phi d\phi + \rho \cos \phi \sin \phi d\rho + \rho^2 \sin^2 \phi d\phi - \rho \cos \phi \sin \phi d\rho \\ &= \rho^2 (\cos^2 \phi + \sin^2 \phi) d\phi \\ &= \rho^2 d\phi \end{aligned}$$

and, analogously,

$$dx_1 \wedge dx_2 = \rho d\rho \wedge d\phi.$$

On $M \times T^2$, choose coordinates (θ_1, θ_2) on the torus part of the manifold. Now we have all ingredients together to construct our contact form. Let

$$\tilde{\alpha} := x_1 d\theta_1 - x_2 d\theta_2 + \alpha.$$

This is a well-defined 1-form on $M \times T^2$ (α is extended to $M \times T^2$ in the obvious way) and we can compute the derivative

$$d\tilde{\alpha} = dx_1 \wedge d\theta_1 - dx_2 \wedge d\theta_2 + d\alpha,$$

hence

$$\begin{aligned} (d\tilde{\alpha})^n &= (n-1)(d\alpha)^{n-1} \wedge (dx_1 \wedge d\theta_1 - dx_2 \wedge d\theta_2) \\ &\quad - n(n-1)(d\alpha)^{n-2} \wedge dx_1 \wedge d\theta_1 \wedge dx_2 \wedge d\theta_2. \end{aligned}$$

In order to verify the contact condition, we compute

$$\begin{aligned} \tilde{\alpha} \wedge (d\tilde{\alpha})^n &= (x_1 d\theta_1 - x_2 d\theta_2 + \alpha) \wedge (n-1)(d\alpha)^{n-1} \wedge (dx_1 \wedge d\theta_1 - dx_2 \wedge d\theta_2) \\ &\quad - (x_1 d\theta_1 - x_2 d\theta_2 + \alpha) \wedge n(n-1)(d\alpha)^{n-2} \wedge dx_1 \wedge d\theta_1 \wedge dx_2 \wedge d\theta_2 \\ &= (n-1)(d\alpha)^{n-1} \wedge (x_1 dx_2 - x_2 dx_1) \wedge d\theta_1 \wedge d\theta_2 \\ &\quad + \underbrace{\alpha \wedge (n-1)(d\alpha)^{n-1} \wedge dx_1 \wedge d\theta_1}_{2n\text{-form on } M} - \underbrace{\alpha \wedge (n-1)(d\alpha)^{n-1} \wedge dx_2 \wedge d\theta_2}_{2n\text{-form on } M} \\ &\quad + n(n-1)\alpha \wedge (d\alpha)^{n-2} \wedge dx_1 \wedge d\theta_1 \wedge dx_2 \wedge d\theta_2 \end{aligned}$$

M has dimension $2n-1$, i.e. the middle term is 0

$$\begin{aligned} &= (n-1)(d\alpha)^{n-1} \wedge \rho^2 d\phi \wedge d\theta_1 \wedge d\theta_2 \\ &\quad + n(n-1)\alpha \wedge (d\alpha)^{n-2} \wedge \rho d\rho \wedge d\phi \wedge d\theta_1 \wedge d\theta_2 \end{aligned}$$

By condition (ii) of definition 1, $(d\alpha)^{n-1}$ must be a positive volume form on the pages. As explained in that definition, the orientation on M is given by ∂_ϕ and the orientation of the page. In particular, $(d\alpha)^{n-1} \wedge \rho d\phi$ is a positive volume form on M . Multiplied with a second ρ -factor, it vanishes along B . As $\theta_1 \wedge \theta_2$ is a positive volume form on T^2 , the first term is non-negative everywhere and positive away from

$$\underbrace{B \times 0}_{\subset B \times D^2 \subset M} \times T^2.$$

Let \mathfrak{b} be a basis of the binding B that is positively ordered. Then, $-\partial_r, \mathfrak{b}$ and (because the binding is odd-dimensional) \mathfrak{b}, ∂_r are positive bases of the page. Clearly, then,

$$\mathfrak{a} := \mathfrak{b}, \partial_r, \partial_\phi, \partial_{\theta_1}, \partial_{\theta_2}$$

is an ordered basis of $M \times T^2$. Using $\rho'(r) \geq 0$ everywhere, we deduce that $d\rho(\partial_r)$ is non-negative. Hence, plugging \mathbf{a} into the second term, we conclude

$$\begin{aligned} & (n(n-1)\alpha \wedge (d\alpha)^{n-2} \wedge \rho d\rho \wedge d\phi \wedge d\theta_1 \wedge d\theta_2)(\mathbf{a}) \\ &= n(n-1)\rho \cdot (\alpha \wedge (d\alpha)^{n-2})(\mathbf{b}) \cdot d\rho(\partial_r) \cdot d\phi(\partial_\phi) \cdot d\theta_1(\partial_{\theta_1}) \cdot d\theta_2(\partial_{\theta_2}) \\ & \geq 0. \end{aligned}$$

By condition (iii) of definition 1, $\alpha \wedge (d\alpha)^{n-2}$ is positive on B . Therefore, the second term is positive on $B \times 0 \times T^2$ (hence also on a neighborhood) and non-negative everywhere else. In total, we have checked the contact condition and $\tilde{\alpha}$ is indeed a contact form on $M \times T^2$. \square

The Thurston-Winkelnkemper construction

Definition 2 (mapping torus). *Let Σ be a smooth manifold with boundary $\partial\Sigma$ and $\phi : \Sigma \rightarrow \Sigma$ a diffeomorphism that is equal to the identity close to $\partial\Sigma$. The mapping torus $\Sigma(\phi)$ is given by $\Sigma \times [0, 2\pi] / \sim$ where*

$$(x, 2\pi) \sim (\phi(x), 0).$$

The generalized mapping torus requires as additional data a smooth function $\bar{\varphi} : \Sigma \rightarrow \mathbb{R}^+$ that is constant near $\partial\Sigma$. Then,

$$\Sigma_{\bar{\varphi}}(\phi) := \Sigma \times \mathbb{R} / \sim \quad \text{where} \quad (x, \theta) \sim (\phi(x), \theta - \bar{\varphi}(x)).$$

Abstract open books Starting with a mapping torus $\Sigma(\phi)$, we can construct an abstract open book $M(\phi)$ with binding $\partial\Sigma$ (see fig. 1)

We define

$$M(\phi) := (\Sigma(\phi) \cup \partial\Sigma \times D^2) / \sim$$

where we identify

$$[x \in \partial\Sigma, \theta] \sim (x, r = 1, \varphi = \theta)$$
